4. Dynamic Setting

Addition and Deletion
$\boldsymbol{M}$ : the set of objects in the give time after a series of addition and deletion

## Remark

- $H(M)$ does no depend on the insertion order of $M$
- The history and the search structure depend on the insertion order

## General Idea

- For each object in $M$, we randomly choose a priority (a real number) from the uniform distribution on the interval $(0,1)$.
- Shuffle (or a priority order) on $M$ is the ordering of objects of $M$ according to the increasing priorities
- Shuffle is exactly the insertion order
- $S_{k}=k^{\text {th }}$ object in the shuffle, and $M^{i}=\left\{S_{1}, S_{2}, \ldots, S_{i}\right\}$
- $\widetilde{H}\left(\operatorname{shuffle}\left(M^{i}\right)\right)$ is the history of $H\left(\operatorname{shuffle}\left(M^{1}\right)\right), H\left(\operatorname{shuffle}\left(M^{2}\right)\right), \ldots$, $H\left(\operatorname{shuffle}\left(M^{i}\right)\right)$

4. Random Binary Tree of Quick-Sort

| $M=$ | $S_{1}$ | $S_{2}$ | $S_{3}$ | $S_{4}$ | $S_{5}$ | $S_{6}$ | $S_{7}$ | $S_{8}$ |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Value | 23 | 11 | 37 | 47 | 29 | 3 | 7 | 19 |
| Priority | 0.1 | 0.3 | 0.4 | 0.5 | 0.6 | 0.8 | 0.9 | 0.95 |

We want to delete $S$ from $M$

## Fact

If a point $v$ is a descendent of a point $u, u$ 's priority is lower than $v$ 's
Case 1: $S$ is a leaf in the sense that its two sons are both intervals

- Combine its two sons into one interval
- replace $S$ with $I$

Case 2: $S$ is an internal node in the sense that at least one of its sons is a point

- Move $S$ to become a leaf and delete it
- Increase $S$ 's priority step by step to prepared $S$ is inserted later
- When $S$ 's priority is higher than one of its sons, a rotation will happen and move $S$ downward one level

## Rotation:

Assume $S$ has two sons $S^{\prime \prime}$ and $S^{\prime \prime}, S^{\prime}$ has low priority than $S^{\prime \prime}$

Repeatedly performing rotations will bring $S$ to the bottom such that we can delete it.

The expected number of rotations is at most the expected depths of the binary tree, which is $O(\log n)$

Adding $S$

- use $\widetilde{H}(M)$ to locate $S$
- Split the interval contains $S$
- Assume $S^{\prime}$ to be the original parent of the interval. Let $S^{\prime}$ be the parent of $S$ and $S$ be the parent of the two new intervals
- Assign $S$ a priority higher than $S^{\prime}$

## Another viewpoint of rotation:

Deleting $S$ from shuffle $(M)$ can be carried out by moving $S$ higher one by one.
$l$ is the number of points with priorities higher than $S$
$M(i)$ is the priority-ordered set obtained from $M$ by moving $S$ higher in the order by $i$ places.
shuffle $(M(0))$, shuffle $(M(1)), \ldots$, shuffle $(M(l))$
$B=M(i-1)$ and $C=M(i)$
Let $S^{\prime}$ be the point just after $S$ in the priority order $B$
$j=m-l+i-1$, i.e., $H(C)=H\left(C^{j}\right)$ and $H(B)=H\left(B^{j}\right)$
$\longrightarrow H\left(B^{j-1}\right) \xrightarrow{S} H\left(B^{j}\right) \xrightarrow{S^{\prime}} H\left(B^{j+1}\right) \longrightarrow H\left(B^{j+2}\right) \longrightarrow$
$=\quad=\quad=$
$\longrightarrow H\left(C^{j-1}\right) \xrightarrow{S^{\prime}} H\left(C^{j}\right) \xrightarrow{S} H\left(C^{j+1}\right) \longrightarrow H\left(C^{j+2}\right) \longrightarrow$

If $H(B)=H(C)$, this operation is free.

- $S$ and $S^{\prime}$ is contained in different intervals of $H\left(B^{j-1}\right)$

$$
H\left(B^{4}\right)=H\left(C^{4}\right)
$$

$$
H\left(B^{6}\right)=H\left(C^{6}\right)
$$

add $S^{\prime}$

add $S$

If we give $S$ a priority above that of $S^{\prime}$, a right rotation can reflect the new shuffle on $M$

4.2 Trapezoidal Decomposition
